Entity-Relationship Model

E/R Diagrams Weak Entity Sets Converting E/R Diagrams to Relations

Purpose of E/R Model

The E/R model allows us to sketch database schema designs.

- Includes some constraints, but not operations.
- Designs are pictures called *entity*relationship diagrams.

 Later: convert E/R designs to relational DB designs.

Framework for E/R

Design is a serious business.
The "boss" knows they want a database, but they don't know what they want in it.
Sketching the key components is an efficient way to develop a working database.

Entity Sets

Entity = "thing" or object.
 Entity set = collection of similar entities.
 Similar to a class in object-oriented languages.
 Attribute = property of (the entities of) an entity set.

 Attributes are simple values, e.g. integers or character strings, not structs, sets, etc.

E/R Diagrams

In an entity-relationship diagram:

- Entity set = rectangle.
- Attribute = oval, with a line to the rectangle representing its entity set.

Entity set Lemonades has two attributes, name and manf (manufacturer).

Each Lemonades entity has values for these two attributes, e.g. (Bud, Anheuser-Busch)

Relationships

- A relationship connects two or more entity sets.
- It is represented by a diamond, with lines to each of the entity sets involved.

Example: Relationships

Bars sell some lemonades.

Drinkers like some lemonades.

Drinkers frequent some bars.

Relationship Set

The current "value" of an entity set is the set of entities that belong to it.
 Example: the set of all bars in our database.
 The "value" of a relationship is a relationship set, a set of tuples with one component for each related entity set.

Example: Relationship Set

For the relationship Sells, we might have a relationship set like:

Bar	Lemonade
Joe's Bar	Bud
Joe's Bar	Miller
Sue's Bar	Bud
Sue's Bar	Pete's Ale
Sue's Bar	Bud Lite

Multiway Relationships

- Sometimes, we need a relationship that connects more than two entity sets.
- Suppose that drinkers will only drink certain lemonades at certain bars.
 - Our three binary relationships Likes, Sells, and Frequents do not allow us to make this distinction.
 - But a 3-way relationship would.

Example: 3-Way Relationship

A Typical Relationship Set

Bar	Drinker	Lemonades
Joe's Bar	Ann	Miller
Sue's Bar	Ann	Bud
Sue's Bar	Ann	Pete's Ale
Joe's Bar	Bob	Bud
Joe's Bar	Bob	Miller
Joe's Bar	Cal	Miller
Sue's Bar	Cal	Bud Lite

Many-Many Relationships

- Focus: binary relationships, such as Sells between Bars and Lemonades.
- In a many-many relationship, an entity of either set can be connected to many entities of the other set.
 - E.g., a bar sells many lemonades; a lemonade is sold by many bars.

In Pictures:

many-many

Many-One Relationships

- Some binary relationships are *many* one from one entity set to another.
- Each entity of the first set is connected to at most one entity of the second set.
- But an entity of the second set can be connected to zero, one, or many entities of the first set.

In Pictures:

many-one

Example: Many-One Relationship

- Favorite, from Drinkers to Lemonades is many-one.
- A drinker has at most one favorite lemonade.
- But a lemonade can be the favorite of any number of drinkers, including zero.

One-One Relationships

- In a one-one relationship, each entity of either entity set is related to at most one entity of the other set.
- Example: Relationship Best-seller between entity sets Manfs (manufacturer) and Lemonades.
 - A lemonade cannot be made by more than one manufacturer, and no manufacturer can have more than one best-seller (assume no ties).

In Pictures:

one-one

Representing "Multiplicity"

Show a many-one relationship by an arrow entering the "one" side. Remember: Like a functional dependency. Show a one-one relationship by arrows entering both entity sets. \mathbf{A} Rounded arrow = "exactly one," i.e., each entity of the first set is related to exactly one entity of the target set.

Example: Many-One Relationship

Example: One-One Relationship

- Consider Best-seller between Manfs and Lemonades.
- Some lemonades are not the best-seller of any manufacturer, so a rounded arrow to Manfs would be inappropriate.

In the E/R Diagram

A lemonade is the bestseller for 0 or 1 manufacturer. A manufacturer has exactly one best seller.

Attributes on Relationships

- Sometimes it is useful to attach an attribute to a relationship.
- Think of this attribute as a property of tuples in the relationship set.

Example: Attribute on Relationship

Price is a function of both the bar and the lemonades, not of one alone.

Equivalent Diagrams Without Attributes on Relationships

- Create an entity set representing values of the attribute.
- Make that entity set participate in the relationship.

Example: Removing an Attribute from a Relationship

Roles

 Sometimes an entity set appears more than once in a relationship.

Label the edges between the relationship and the entity set with names called *roles*.

Example: Roles

Relationship Set

Example: Roles

Relationship Set

Buddy1	Buddy2
Bob	Ann
Joe	Sue
Ann	Bob
Joe	Moe

Subclasses

- Subclass = special case = fewer entities = more properties.
- Example: Ales are a kind of lemonade.
 - Not every lemonade is an ale, but some are.
 - Let us suppose that in addition to all the properties (attributes and relationships) of lemonades, ales also have the attribute color.

Subclasses in E/R Diagrams

Assume subclasses form a tree.
 I.e., no multiple inheritance.
 Isa triangles indicate the subclass relationship.

Point to the superclass.

Example: Subclasses

E/R Vs. Object-Oriented Subclasses

In OO, objects are in one class only.

- Subclasses inherit from superclasses.
- In contrast, E/R entities have representatives in all subclasses to which they belong.
 - Rule: if entity e is represented in a subclass, then e is represented in the superclass (and recursively up the tree).

Example: Representatives of Entities

Keys

- A key is a set of attributes for one entity set such that no two entities in this set agree on all the attributes of the key.
 - It is allowed for two entities to agree on some, but not all, of the key attributes.

We must designate a key for every entity set.

Keys in E/R Diagrams

Underline the key attribute(s).
 In an Isa hierarchy, only the root entity set has a key, and it must serve as the key for all entities in the hierarchy.

Example: name is Key for Lemonades

Example: a Multi-attribute Key

 Note that hours and room could also serve as a key, but we must select only one key.

Weak Entity Sets

Occasionally, entities of an entity set need "help" to identify them uniquely. Entity set E is said to be weak if in order to identify entities of E uniquely, we need to follow one or more manyone relationships from E and include the key of the related entities from the connected entity sets.

Example: Weak Entity Set

name is almost a key for football players, but there might be two with the same name.
number is certainly not a key, since players on two teams could have the same number.
But number, together with the team name related to the player by Plays-on should be unique.

In E/R Diagrams

- Double diamond for *supporting* many-one relationship.
- Double rectangle for the weak entity set.

Weak Entity-Set Rules

- A weak entity set has one or more many-one relationships to other (supporting) entity sets.
 - Not every many-one relationship from a weak entity set need be supporting.
 - But supporting relationships must have a rounded arrow (entity at the "one" end is guaranteed).

Weak Entity-Set Rules – (2)

The key for a weak entity set is its own underlined attributes and the keys for the supporting entity sets.

 E.g., (player) number and (team) name is a key for Players in the previous example.

Design Techniques

- 1. Avoid redundancy.
- 2. Limit the use of weak entity sets.
- 3. Don't use an entity set when an attribute will do.

Avoiding Redundancy

- Redundancy = saying the same thing in two (or more) different ways.
- Wastes space and (more importantly) encourages inconsistency.
 - Two representations of the same fact become inconsistent if we change one and forget to change the other.
 - Recall anomalies due to FD's.

Example: Good

This design gives the address of each manufacturer exactly once.

Example: Bad

This design states the manufacturer of a lemonade twice: as an attribute and as a related entity.

This design repeats the manufacturer's address once for each lemonade and loses the address if there are temporarily no lemonades for a manufacturer.

Entity Sets Versus Attributes

- An entity set should satisfy at least one of the following conditions:
 - It is more than the name of something; it has at least one nonkey attribute.

or

 It is the "many" in a many-one or manymany relationship.

Example: Good

 Manfs deserves to be an entity set because of the nonkey attribute addr.

•Lemonades deserves to be an entity set because it is the "many" of the many-one relationship ManfBy.

Example: Good

There is no need to make the manufacturer an entity set, because we record nothing about manufacturers besides their name.

Example: Bad

Since the manufacturer is nothing but a name, and is not at the "many" end of any relationship, it should not be an entity set.

Don't Overuse Weak Entity Sets

- Beginning database designers often doubt that anything could be a key by itself.
 - They make all entity sets weak, supported by all other entity sets to which they are linked.
- In reality, we usually create unique ID's for entity sets.
 - Examples include social-security numbers, automobile VIN's etc.

When Do We Need Weak Entity Sets?

- The usual reason is that there is no global authority capable of creating unique ID's.
- Example: it is unlikely that there could be an agreement to assign unique player numbers across all football teams in the world.

From E/R Diagrams to Relations

- Entity set -> relation.
 - Attributes -> attributes.
- Relationships -> relations whose attributes are only:
 - The keys of the connected entity sets.
 - Attributes of the relationship itself.

Entity Set -> Relation

Relation: Lemonades(name, manf)

Relationship -> Relation

Combining Relations

- OK to combine into one relation:
 - 1. The relation for an entity-set *E*
 - 2. The relations for many-one relationships of which *E* is the "many."
- Example: Drinkers(name, addr) and Favorite(drinker, lemonade) combine to make Drinker1(name, addr, favLemonade).

Risk with Many-Many Relationships

 Combining Drinkers with Likes would be a mistake. It leads to redundancy, as:

Handling Weak Entity Sets

Relation for a weak entity set must include attributes for its complete key (including those belonging to other entity sets), as well as its own, nonkey attributes.

A supporting relationship is redundant and yields no relation (unless *it* has attributes).

Example: Weak Entity Set -> Relation

63

Subclasses: Three Approaches

- Object-oriented : One relation per subset of subclasses, with all relevant attributes.
- *2. Use nulls* : One relation; entities have NULL in attributes that don't belong to them.
- *3. E/R style* : One relation for each subclass:
 - Key attribute(s).
 - Attributes of that subclass.

Example: Subclass -> Relations

Object-Oriented

name	manf
Bud	Anheuser-Busch
Lemonades	

name	manf	color
Summerbrew	Pete's	dark
Ales		

Good for queries like "find the color of ales made by Pete's."

E/R Style

name	manf
Bud	Anheuser-Busch
Summerbrew	Pete's
	Lemonades

name	color
Summerbrew	dark
Ales	

Good for queries like "find all lemonades (including ales) made by Pete's."

Using Nulls

name	manf	color
Bud	Anheuser-Busch	NULL
Summerbrew	Pete's	dark
Lemonades		

Saves space unless there are *lots* of attributes that are usually NULL.
